

Fire

One-page repo summary based on README.md, index.html, script.js, style.css, and locales/*.json

What It Is

Fire is a FIRE calculator for couples from Europe.

It is a static browser app that models portfolio growth and drawdown using ages, contributions, expenses, pensions, inflation, and returns.

Who It Is For

Primary user/persona: couples in Europe comparing shared retirement scenarios and long-term financial independence tradeoffs.

What It Does

- Models two people with separate current, retirement, pension, and end ages.
- Charts portfolio value across three phases: 2 work, 1 work, and 0 work.
- Adjusts for current assets, annual return, annual contributions, annual spending, and inflation.
- Adds pension income for both people during retirement years.
- Supports three extra-cost entries with configurable start and end years.
- Can show projections in nominal values or today's purchasing power.
- Loads English, Dutch, French, and German labels and saves slider inputs in localStorage.

How It Works

- UI shell: index.html defines a three-panel slider interface plus a central canvas for the chart.
- Presentation: style.css controls desktop/mobile layout, panel styling, and slider appearance.
- Logic: script.js initializes i18next, restores localStorage values, recalculates yearly data, and redraws Chart.js on input changes.
- Data flow: user input -> DOM event listeners -> calculatePortfolioGrowth(...) -> datasets by work phase -> chart and tooltips.
- Services/data: locale JSON files in locales/ are fetched by i18next; no repo-hosted backend, database, or auth flow found in repo.

How To Run

- Open the repo root containing index.html, script.js, style.css, and locales/.
- Serve the folder over HTTP, because script.js loads /locales/{{lng}}.json and index.html references CDN-hosted Chart.js and i18next script.
- Open the served index.html page in a browser and adjust the sliders.
- Exact start command, package manifest, deployment setup, and test instructions: Not found in repo.
